

DESCRIPTION

MARCHANTIALES-DERIVED UNSATURATED FATTY ACID SYNTHETASE GENES AND USE OF THE SAME

TECHNICAL FIELD

5 The present invention relates to *Marchantiales*
(*Marchantia polymorpha*)-derived unsaturated fatty acid
synthetase genes, i.e. genes of $\Delta 5$ fatty acid desaturase, $\Delta 6$
fatty acid desaturase, and $\Delta 6$ fatty-acid-chain elongase, and
use thereof.

10

BACKGROUND ART

Polyunsaturated fatty acids (PUFAs) such as arachidonic
acid, eicosapentaenoic acid (hereinafter referred to as "EPA"
as appropriate) are contained in lipids of the cell membrane of
15 humans, notably in the nervous system. These
polyunsaturated fatty acids act as a precursor of a bioactive
substance such as prostaglandin and leukotoriene, and are
very important pharmacological substances. In recent years,
health foods containing arachidonic acid and EPA have been
20 commercially available. In addition, fatty acids, which are

used as a source material of detergents and biodegradable plastics, have captured the spotlight as material substances.

5 Polyunsaturated fatty acids are currently produced by extraction from cultured microorganisms or fish oil. This raises problems of high production cost, increased energy consumption and waste, and limited fish resources particularly in methods using fish oil.

10 The biosynthesis of arachidonic acid and EPA is believed to occur in a series of reactions involving $\Delta 6$ desaturation, chain elongation, and $\Delta 5$ desaturation, with linoleic acid and α -linolenic acid being starting materials of the reactions yielding the arachidonic acid and eicosapentaenoic acid, respectively. These reactions are catalyzed by a $\Delta 6$ fatty acid desaturase (" $\Delta 6$ desaturase" hereinafter), $\Delta 6$ fatty-acid-chain elongase (" $\Delta 6$ chain elongase" hereinafter), and $\Delta 5$ fatty acid desaturase (" $\Delta 5$ desaturase" hereinafter), respectively.

20 A gene for the $\Delta 6$ desaturase is cloned from several plant species. For example, the gene has been cloned from *Phaeodactylum tricornutum*, *Physcomitrella patens*, *ceratodon purpureus*, borage, *lithospermum erythrorhizon*, primrose, and anemone. Apart from plants, the $\Delta 6$ desaturase gene has also been cloned from filamentous fungi, nematodes, cyanobacteria, rats, and humans (see Non-Patent Publication

1: Eur. J. Biochem. 269, p4105, 2002; Non-Patent Publication
2: Plant J. 15, p39, 1998; Non-Patent Publication 3: Eur. J.
Biochem., 267. p3801, 2000; Non-Patent Publication 4: Proc.
Natl. Acad. Sci. USA 94, p4211, 1997; Non-Patent Publication
5 5: Lipids 37, 417, 2002; Non-Patent Publication 6: FEBS Lett.
542, p100, 2003; Non-Patent Publication 7: Whitney et al.,
Planta Epub 2003; Non-Patent Publication 8: Lipids 34, p649,
1999; Non-Patent Publication 9: Gene, 238, p445 1999;
Non-Patent Publication 10: Biochem J. 330, p611 1998;
10 Non-Patent Publication 11: Plant Mol. Biol., 22, p293 1993;
Non-Patent Publication 12: Biochem. Biophys. res. Commun.
255, p575, 1999; and Non-Patent Publication 13: J. Biol.
Chem. 274, p471, 1999). All of these $\Delta 6$ desaturases cloned
from these organisms, except that obtained from
15 cyanobacteria, have a cytochrome b5 domain at their
N-terminus.

A gene of the $\Delta 6$ chain elongase was originally cloned
from filamentous fungi and nematodes (see Non-Patent
Publication 14: Proc. Natl. Acad. Sci. USA 97, p8284, 2000;
20 and Non-Patent Publication 15: Proc. Natl. Acad. Sci. USA 97,
p6421, 2000). In plants, the gene has been cloned only from
Physcomitrella patens (see Non-Patent Publication 16: Plant J.
31, p255, 2002).

In yeasts (*Saccharomyces cerevisiae*), there exist ELO2 protein and ELO3 protein, which are involved in the synthesis of a long-chain saturated acyl-chain of sphingolipids (see Non-Patent Publication 17: J. Biol. Chem., 272, p17376, 1997). The $\Delta 6$ chain elongase has an amino acid sequence homologous to the ELO2 protein and ELO3 protein. On the other hand, in plants, there exists β -ketoacyl-CoA synthase (KCS), which is another type of fatty-acid-chain elongase. This enzyme catalyzes the elongation of long-chain saturated and monounsaturated fatty acids (see Non-Patent Publication 15 and Non-Patent Publication 18: Plant Cell 7, p309, 1995). However, the KCS gene is not evolutionary related to the $\Delta 6$ chain elongase gene, or yeast ELO2 and ELO3 genes (see Non-Patent Publications 15 and 16).

A gene of the $\Delta 5$ desaturase was originally cloned from filamentous fungi (Non-Patent Publication 19: J. Biol. Chem. 273, p29360, 1998; and Non-Patent Publication 20: J. Biol. Chem. 273, p19055). The $\Delta 5$ desaturase has a cytochrome b5 domain at the N-terminus as does the $\Delta 6$ desaturase. The $\Delta 5$ desaturase gene has also been cloned from *Phaeodactylum tricornutum*, nematodes, rats, humans, *Physcomitrella patens*, and others (see Non-Patent Publication 1; Non-Patent Publication 21: FEBS Lett. 439, p215, 1998; Non-Patent

Publication 22: Arch. Biochem. Biophys. 391, p8, 2001;
Non-Patent Publication 23: J. Biol. Chem. 274, p37335, 1999;
and Non-Patent Publication 24: J. Biol. Chem. 278, 35115,
2003).

5 Terrestrial plants are classified into bryophytes
(*Bryophyta*), pteridophytes, gymnosperms, and angiosperms.
Among these groups of terrestrial plants, bryophytes are
known to have branched off first, and they are classified into
three groups: Mosses (class *Bryosida*), Liverworts (class
10 *Hepaticopsida*), and Hornwortz. *Marchantia polymorpha* is
taxonomically closest to *Physcomitrella patens* among the
foregoing organisms, but the latter belongs to class *Bryosida*
while the former belongs to subclass *Marchantiidae* of class
Hepaticopsida. It is certain that the foregoing three groups
15 were branched off at least about 430 million years ago.
Therefore, contrary to their common name "moss," the
difference between *Physcomitrella patens* and *Marchantia*
polymorpha is evolutionary far too great to be called as a
difference, as compared with the difference, for example,
20 between *Arabidopsis thaliana* and rice, which are believed to
have branched off 200 million years ago (see Non-Patent
Publication 25: 110361514143968_0.html).

As a *Marchantia polymorpha*-derived polyunsaturated

fatty acid synthetase gene, KCS-like MpFAE2 and MpFAE3 chain elongase genes have been obtained (see Non-Patent Publication 26: Biosci. Biotechnol. Biochem. 67, p605, 2003; and Non-Patent Publication 27: Biosci. Biotechnol. Biochem. 67, p1667, 2003). However, MpFAE2 and MpFAE3 are not $\Delta 6$ chain elongase genes.

As described earlier, many polyunsaturated fatty acid biosynthetic genes are cloned from various species of organisms. However, there is only a few reports in which polyunsaturated fatty acids having 20 or more carbon atoms with a degree of unsaturation 4 or greater, such as arachidonic acid and EPA, were produced in plants. As an example, it has been reported that *Phaeodactylum tricornutum*-derived $\Delta 6$ desaturase and $\Delta 5$ desaturase, and a *Physcomitrella patens*-derived $\Delta 6$ chain elongase were expressed in *Linum usitatissimum* to produce arachidonic acid and EPA. However, this is not described in detail (see Non-Patent Publication 24).

As described earlier, polyunsaturated fatty acids, such as arachidonic acid and EPA, are produced by extraction from cultured microorganisms or fish oil. This raises problems of high production cost, increased energy consumption and waste, and limited fish resources. Polyunsaturated fatty acids

such as arachidonic acid and EPA have a plurality of double bonds in the molecule. This unique characteristic enables these fatty acids to be used in various industrial products (e.g. films, biodegradable plastics, functional fabrics, lubricating oil, and material substance for detergents). By producing such polyunsaturated fatty acids in transgenic plants, it will be possible to reduce production cost and realize a more environmentally friendly production process. Once the polyunsaturated fatty acids are mass-produced with oil plants by genetic recombinant techniques, it will be possible to advantageously use such oil plants as inexpensive source materials for many different purposes.

However, in the expression of foreign genes in plants, it is difficult to predict how well the genes will function in the plants because the gene expression involves transcription, translation, and modifications. Further, in the expression of more than one foreign gene, it is envisaged that the expressed genes will function more desirably when they come from a single species of plant, as opposed to different plant species as in the case of Non-Patent Publication 24. Further, *Marchantia polymorpha*, which belongs to phylum *Bryophyta*--the first terrestrial plants--has been receiving attention as a model of higher plants, and their genes are

expected to function well in other plants. Therefore, once *Marchantia polymorpha*-derived polyunsaturated fatty acid synthetase genes, i.e. $\Delta 5$ desaturase gene, $\Delta 6$ desaturase gene, and $\Delta 6$ chain elongase gene are obtained, it will be possible to efficiently accumulate arachidonic acid and EPA in plants by introducing these genes into plants.

The $\Delta 5$ desaturase gene, $\Delta 6$ desaturase gene, and $\Delta 6$ chain elongase gene have been cloned from *Physcomitrella patens*, which also belong to phylum *bryophyta* as does *Marchantia polymorpha*. However, since *Marchantia polymorpha* and *Physcomitrella patens* are evolutionary very distant species, it is not easy to obtain *Marchantia polymorpha* genes using *Physcomitrella patens* genes with the current level of technology.

DISCLOSURE OF INVENTION

The present invention was made in view of the foregoing problems, and an object of the invention is to provide *Marchantiales* (*Marchantia polymorpha*)-derived unsaturated fatty acid synthetase genes, specifically, $\Delta 5$ desaturase gene, $\Delta 6$ desaturase gene, and $\Delta 6$ chain elongase gene, that can produce arachidonic acid or EPA in higher plants. The invention also provides a method of use of such genes.

In accomplishing the present invention, the inventors of the invention identified genes that encode the $\Delta 5$ desaturase, $\Delta 6$ desaturase, and $\Delta 6$ chain elongase, using cDNA clones derived from *Marchantiales* (*Marchantia polymorpha*), and successfully transferred and expressed these genes in methylotrophic yeasts (*Pichia pastoris*). As a result, the inventors have found that proteins expressed by these genes had enzyme activities of the $\Delta 5$ desaturase, $\Delta 6$ desaturase, and $\Delta 6$ chain elongase, respectively. Specifically, the present invention includes:

(1) A *Marchantiales*-derived gene that hybridizes under stringent conditions with all of or part of a DNA nucleotide sequence, or its complementary sequence, of SEQ ID NO: 1, and encodes a protein having a $\Delta 6$ fatty acid desaturating activity.

(2) A gene that encodes a *Marchantiales*-derived protein having a $\Delta 6$ fatty acid desaturating activity, and that (a) consists of a nucleotide sequence of SEQ ID NO: 1, or (b) hybridizes under stringent conditions with a DNA nucleotide sequence, or its complementary sequence, of SEQ ID NO: 1.

(3) A gene that encodes a *Marchantiales*-derived protein having a $\Delta 6$ fatty acid desaturating activity, and that (a) consists of a nucleotide sequence of from the 253rd to 1698th

nucleotides of SEQ ID NO: 1, or (b) hybridizes under stringent conditions with a DNA nucleotide sequence of from the 253rd to 1698th nucleotides, or its complementary sequence, of SEQ ID NO: 1.

5 (4) A gene that encodes a *Marchantiales*-derived protein having a $\Delta 6$ fatty acid desaturating activity, and that (a) encodes a protein with an amino acid sequence of SEQ ID NO: 2, or (b) encodes a protein with an amino acid sequence that has been modified by substitution, deletion, insertion, and/or
10 addition of one or more amino acids of SEQ ID NO: 2.

 (5) A *Marchantiales*-derived gene that hybridizes under stringent conditions with all of or part of a DNA nucleotide sequence, or its complementary sequence, of SEQ ID NO: 3, and encodes a protein having a $\Delta 6$ chain elongating activity.

15 (6) A gene that encodes a *Marchantiales*-derived protein having a $\Delta 6$ chain elongating activity, and that (a) consists of a nucleotide sequence of SEQ ID NO: 3, or (b) hybridizes under stringent conditions with a DNA nucleotide sequence, or its complementary sequence, of SEQ ID NO: 3.

20 (7) A gene that encodes a *Marchantiales*-derived protein having a $\Delta 6$ chain elongating activity, and that (a) consists of a nucleotide sequence of from the 194th to 1066th nucleotides of SEQ ID NO: 1, or (b) hybridizes under stringent

conditions with a DNA nucleotide sequence of from the 194th to 1066th nucleotides, or its complementary sequence, of SEQ ID NO: 1.

5 (8) A gene that encodes a *Marchantiales*-derived protein having a $\Delta 6$ chain elongating activity, and that (a) encodes a protein with an amino acid sequence of SEQ ID NO: 4, or (b) encodes a protein with an amino acid sequence that has been modified by substitution, deletion, insertion, and/or addition of one or more amino acids of SEQ ID NO: 4.

10 (9) A *Marchantiales*-derived gene that hybridizes under stringent conditions with all of or part of a DNA nucleotide sequence, or its complementary sequence, of SEQ ID NO: 5, and encodes a protein having a $\Delta 5$ fatty acid desaturating activity.

15 (10) A gene that encodes a *Marchantiales*-derived protein having a $\Delta 5$ fatty acid desaturating activity, and that (a) consists of a nucleotide sequence of SEQ ID NO: 5, or (b) hybridizes under stringent conditions with a DNA nucleotide sequence, or its complementary sequence, of SEQ ID NO: 5.

20 (11) A gene that encodes a *Marchantiales*-derived protein having a $\Delta 5$ fatty acid desaturating activity, and that (a) consists of a nucleotide sequence of from the 375th to 1829th nucleotides of SEQ ID NO: 5, or (b) hybridizes under stringent

conditions with a DNA nucleotide sequence of from 375th to 1829th nucleotides, or its complementary sequence, of SEQ ID NO: 5.

5 (12) A gene that encodes a *Marchantiales*-derived protein having a $\Delta 5$ fatty acid desaturating activity, and that (a) encodes a protein with an amino acid sequence of SEQ ID NO: 6, or (b) encodes a protein with an amino acid sequence that has been modified by substitution, deletion, insertion, and/or addition of one or more amino acids of SEQ ID NO: 6.

10 (13) A protein encoded by a gene of any one of genes (1) through (12).

(14) A protein (a) consisting of an amino acid sequence of SEQ ID NO: 2, or (b) consisting of an amino acid sequence that has been modified by substitution, deletion, insertion, and/or addition of one or more amino acids of SEQ ID NO: 2, and having a $\Delta 6$ fatty acid desaturating activity.

15 (15) A protein (a) consisting of an amino acid sequence of SEQ ID NO: 4, or (b) consisting of an amino acid sequence that has been modified by substitution, deletion, insertion, and/or addition of one or more amino acids of SEQ ID NO: 4, and having a $\Delta 6$ chain elongating activity.

20 (16) A protein (a) consisting of an amino acid sequence of SEQ ID NO: 6, or (b) consisting of an amino acid sequence

that has been modified by substitution, deletion, insertion, and/or addition of one or more amino acids of SEQ ID NO: 6, and having a $\Delta 5$ fatty acid desaturating activity.

5 (17) An antibody which recognizes a protein of any one of proteins (13) through (16).

(18) A recombinant expression vector which comprises a gene of any one of genes (1) through (12).

(19) A transformant into which a gene of any one of genes (1) through (12) is introduced.

10 (20) A plant into which at least a gene of any one of genes (1) through (12) is expressibly introduced, its progeny or vegetatively propagated plants having the same characteristics, or a tissue of the plant.

15 (21) A plant into which at least a gene of any one of genes (1) through (12) is expressibly introduced and whose fatty acid composition is thereby modified, its progeny or vegetatively propagated plants having the same characteristics, or a tissue of the plant.

(22) A reproductive material of a plant (20) or (21).

20 (23) A method of producing fatty acids, using a plant or a plant tissue of (21).

(24) A material substance which includes at least one compound selected from the group consisting of: γ -linolenic

acid; dihomog-linolenic acid; arachidonic acid; stearidonic acid; eicosatetraenoic acid; and eicosapentaenoic acids, which are obtained by a method of (23).

5 (25) A method of modifying a fatty acid composition, using at least a gene of any one of (1) through (12).

(26) A gene detecting instrument comprising as a probe at least a portion of a nucleotide sequence, or its complementary sequence, of a gene of any one of (1) through (12).

10 (27) A screening method of a gene or substance that regulates a protein of any one of (13) through (16), using a protein of any one of (13) through (16).

(28) A gene or substance obtained by a screening method of (27).

15 It is to be noted that, in the present invention, the nucleotides A, C, G, and T indicate adenine, cytosine, guanine, and thymine, respectively, unless otherwise specified.

Other objects, features, and advantages of the invention will be made clear by the descriptions below. Benefits of the invention will also be made clear by the description referring to the attached drawing.

20

BRIEF DESCRIPTION OF DRAWINGS

Fig. 1 is an explanatory drawing illustrating a procedure of constructing a construct in which expression cassettes of MpDES6 gene, MpELO1 gene, and MpDES5 gene used in Example 6 are joined to one another.

5

BEST MODE FOR CARRYING OUT THE INVENTION

The following will describe an embodiment of the present invention. It is to be noted that the invention is not limited in any way by the following description.

10

Specifically, the following describes, in order of appearance, synthetic pathways of arachidonic acid and eicosapentaenoic acid (EPA), genes and proteins according to the invention, methods of obtaining proteins and genes of the invention, and methods of use (usefulness) of genes and proteins according to the invention.

15

(1) Synthetic pathways of arachidonic acid and eicosapentaenoic acid (EPA)

20

The biosynthesis of arachidonic acid and eicosapentaenoic acid (EPA) is believed to occur in a series of reactions involving $\Delta 6$ desaturation, $\Delta 6$ chain elongation, and $\Delta 5$ desaturation, with linoleic acid and α -linolenic acid being starting materials of the reactions yielding the arachidonic acid and eicosapentaenoic acid, respectively. These reactions

are catalyzed by $\Delta 6$ desaturase, $\Delta 6$ chain elongase, and $\Delta 5$ desaturase, and are called an n-6 pathway (arachidonic acid synthetic pathway), or an n-3 pathway (EPA synthetic pathway).

5 Previous reports suggest that the $\Delta 6$ desaturase, $\Delta 6$ chain elongase, and $\Delta 5$ desaturase are involved in both n-6 pathway and n-3 pathway. Specifically, the $\Delta 6$ desaturase in the n-6 pathway converts linoleic acid ($18:2\Delta^{9,12}$, containing 18 carbon atoms, and two double bonds at positions 9 and 12
10 (the same notation will be used below)) into γ -linolenic acid (GLA; $18:3\Delta^{6,9,12}$). In the n-3 pathway, the $\Delta 6$ desaturase converts α -linolenic acid (ALA; $18:3\Delta^{9,12,15}$) into stearidonic acid (STA; $18:4\Delta^{6,9,12,15}$). The $\Delta 6$ chain elongase in the n-6 pathway converts GLA into dihomo- γ -linolenic acid (DGLA;
15 $20:3\Delta^{8,11,14}$), and in the n-3 pathway converts STA into eicosatetraenoic acid (ETA; $20:4\Delta^{8,11,14,17}$). The $\Delta 5$ desaturase in the n-6 pathway converts DGLA into arachidonic acid ($20:4\Delta^{5,8,11,14}$), and in the n-3 pathway converts ETA into eicosapentaenoic acid (EPA; $20:5\Delta^{5,8,11,14,17}$)

20 (2) Genes according to the present invention

 [$\Delta 6$ desaturase gene according to the invention]

 A $\Delta 6$ desaturase gene according to the present invention is a *Marchantiales*-derived gene that encodes a protein having

a $\Delta 6$ fatty acid desaturating activity. Specifically, the gene satisfies the following conditions:

1. A gene with the nucleotide sequence of SEQ ID NO: 1;
2. A gene that hybridizes under stringent conditions
5 with DNA of a nucleotide sequence, or its complementary sequence, of SEQ ID NO: 1;
3. A gene that hybridizes under stringent conditions with part of DNA of a nucleotide sequence, or its complementary sequence, of SEQ ID NO: 1;
- 10 4. A gene with a nucleotide sequence of from the 253rd to 1698th nucleotides of a nucleotide sequence of SEQ ID NO: 1, wherein this portion of the nucleotide sequence is translated into a protein with an amino acid sequence of SEQ ID NO: 2;
- 15 5. A gene that hybridizes under stringent conditions with a nucleotide sequence of from the 253rd to 1698th nucleotides of a nucleotide sequence, or its complementary sequence, of SEQ ID NO: 1;
- 20 6. A gene that encodes a protein with an amino acid sequence of SEQ ID NO: 2; and
7. A gene that encodes a protein with an amino acid sequence that has been modified by substitution, deletion, insertion, and/or addition of one or more amino acids of the

amino acid sequence of SEQ ID NO: 2.

[$\Delta 6$ chain elongase gene according to the present invention]

5 A $\Delta 6$ chain elongase gene according to the present invention is a *Marchantiales*-derived gene that encodes a protein having a $\Delta 6$ fatty-acid-chain elongating activity. Specifically, the gene satisfies the following conditions:

1. A gene with a nucleotide sequence of SEQ ID NO: 3;

10 2. A gene that hybridizes under stringent conditions with DNA of the nucleotide sequence, or its complementary sequence, of SEQ ID NO: 3;

3. A gene that hybridizes under stringent conditions with part of DNA of a nucleotide sequence, or its complementary sequence, of SEQ ID NO: 3;

15 4. A gene with a nucleotide sequence of from the 194th to 1066th nucleotides of a nucleotide sequence of SEQ ID NO: 3, wherein this portion of the nucleotide sequence is translated into a protein with an amino acid sequence of SEQ ID NO: 4;

20 5. A gene that hybridizes under stringent conditions with a nucleotide sequence of from the 194th to 1066th nucleotides of a nucleotide sequence, or its complementary sequence, of SEQ ID NO: 3;

6. A gene that encodes a protein with an amino acid sequence of SEQ ID NO: 4; and

7. A gene that encodes a protein with an amino acid sequence that has been modified by substitution, deletion,
5 insertion, and/or addition of one or more amino acids of the amino acid sequence of SEQ ID NO: 4.

[Δ 5 desaturase gene according to the invention]

A Δ 5 desaturase gene according to the present invention is a *Marchantiales*-derived gene that encodes a protein having
10 a Δ 5 fatty acid desaturating activity. Specifically, the gene satisfies the following conditions:

1. A gene with a nucleotide sequence of SEQ ID NO: 5;

2. A gene that hybridizes under stringent conditions with DNA of a nucleotide sequence, or its complementary
15 sequence, of SEQ ID NO: 5;

3. A gene that hybridizes under stringent conditions with part of DNA of a nucleotide sequence, or its complementary sequence, of SEQ ID NO: 5;

4. A gene with a nucleotide sequence of from the 375th
20 to 1829th nucleotides of a nucleotide sequence of SEQ ID NO: 5, wherein this portion of the nucleotide sequence is translated into a protein with an amino acid sequence of SEQ ID NO: 6;

5. A gene that hybridizes under stringent conditions with a nucleotide sequence of from the 375th to 1829th nucleotides, or its complementary sequence, of SEQ ID NO: 5;

6. A gene that encodes a protein with an amino acid sequence of SEQ ID NO: 6; and

7. A gene that encodes a protein with an amino acid sequence that has been modified by substitution, deletion, insertion, and/or addition of one or more amino acids of the amino acid sequence of SEQ ID NO: 6.

As used herein, "under stringent conditions" means that hybridization takes place only when there is at least 90% identity, preferably at least 95% identity, and more preferably at least 97% identity.

Hybridization may be carried out by a conventional method, as described in J. Sambrook et al. Molecular Cloning, A Laboratory Manual, 2nd Ed., Cold Spring Harbor Laboratory (1989), for example. Generally, the level of stringency increases with increase in temperature and/or decrease in salt concentration (more difficult to hybridize), and more homologous genes are obtained. Hybridization conditions are not particularly limited, and hybridization can be suitably carried out under various conditions known in the art. For example, hybridization can be carried out under the following

conditions: 42°C, 6× SSPC, 50% formamide, 1% SDS, 100 µg/ml salmon sperm DNA, 5 × Denhardt's solution (1 × SSPE; 0.18 M sodium chloride, 10 mM sodium phosphate, pH 7.7, 1 mM EDTA).

5 As the term is used herein, "*Marchantiales*" is not just limited to *Marchantia polymorpha*, but includes all organisms that belong to subclass *Marchantiidae* and order *Marchantiales*. Among such *Marchantiales* organisms, the following species are known to contain super long
10 polyunsaturated fatty acids (Prog. Lipid Res. 32, p281, 1993): *Monoclea forsteri* (*Monocleales*), *Corsinia coriandrina* (*Marchantiales*), *Oximitra paleacea* (*Marchantiales*), *Ricciocarpos natans* (*Marchantiales*), *Ricca huebeneriana* (*Marchantiales*), *Ricca fluitans* (*Marchantiales*), *Ricca duplex*
15 (*Marchantiales*), *Ricca canaliculata* (*Marchantiales*), *Ricca bifurca* (*Marchantiales*), *Ricca ciliifera* (*Marchantiales*), *Ricca glauca* (*Marchantiales*), *Ricca sorocarpa* (*Marchantiales*), *Ricca warnstorffii* (*Marchantiales*), *Ricca michelii* (*Marchantiales*), *Ricca papillosa* (*Marchantiales*), and *Ricca zachariae*
20 (*Marchantiales*). With the current techniques, the $\Delta 6$ desaturase, $\Delta 6$ chain elongase, and $\Delta 5$ desaturase genes can readily be obtained from these organisms. For example, genes of related species encoding enzymes that exhibit the same

function are known to cross-hybridize.

Genes according to the present invention are not limited to double-stranded DNA, and may be the sense strand or anti-sense strand of double-stranded DNA or RNA. The anti-sense strand may be used as a probe or anti-sense compound. For DNA, cDNA or genomic DNA obtained by cloning techniques, chemical synthesis techniques, or a combination of these different techniques may be used. Further, genes according to the present invention may include a sequence of an untranslated region (UTR), or a vector sequence (including expression vector sequence).

(3) Proteins according to the present invention

[$\Delta 6$ desaturase protein according to the present invention]

A $\Delta 6$ desaturase protein according to the present invention is a *Marchantiales*-derived protein that has a $\Delta 6$ fatty acid desaturating activity. Specifically, the protein satisfies the following conditions:

1. A protein encoded by the $\Delta 6$ fatty acid desaturase gene of the invention defined in section (2) above;
2. A protein with an amino acid sequence of SEQ ID NO: 2; and
3. A protein with an amino acid sequence that has been

modified by substitution, deletion, insertion, and/or addition of one or more amino acids of the amino acid sequence of SEQ ID NO: 2.

5 [Δ6 chain elongase protein according to the present invention]

A Δ6 chain elongase according to the present invention is a *Marchantiales*-derived protein that has a Δ6 chain elongating activity. Specifically, the protein satisfies the following conditions:

10 1. A protein encoded by the Δ6 chain elongase gene of the invention defined in section (2) above;

2. A protein with an amino acid sequence of SEQ ID NO: 4; and

15 3. A protein with an amino acid sequence that has been modified by substitution, deletion, insertion, and/or addition of one or more amino acids of the amino acid sequence of SEQ ID NO: 4.

[Δ5 desaturase protein according to the present invention]

20 A Δ5 desaturase protein according to the present invention is a *Marchantiales*-derived protein that has a Δ5 fatty acid desaturating activity. Specifically, the protein satisfies the following conditions:

1. A protein encoded by the $\Delta 5$ fatty acid desaturase gene of the invention defined in section (2) above;

2. A protein with an amino acid sequence of SEQ ID NO: 6; and

5 3. A protein with an amino acid sequence that has been modified by substitution, deletion, insertion, and/or addition of one or more amino acids of the amino acid sequence of SEQ ID NO: 6.

10 As the term is used herein, the " $\Delta 6$ fatty acid desaturating activity" means that the enzyme has substrate specificity to linoleic acid and α -linolenic acid, and converts these acids to γ -linolenic acid and stearidonic acid, respectively. As the term is used herein, " $\Delta 6$ chain elongating activity" means that the enzyme has substrate specificity to
15 γ -linolenic acid and stearidonic acid, and converts these acids to dihom- γ -linolenic acid and eicosatetraenoic acid, respectively. Further, as the term is used herein, the " $\Delta 5$ fatty acid desaturating activity" means that the enzyme has
20 substrate specificity to dihom- γ -linolenic acid and eicosatetraenoic acid, and converts these acids to arachidonic acid and eicosapentaenoic acid (EPA), respectively.

As used herein, "substitution, deletion, insertion, and/or addition of one or more amino acids" means

substitution, deletion, insertion, and/or addition of preferably no more than 10, more preferably no more than 7, and further preferably no more than 5 amino acids, as enabled by a mutant protein producing method known in the art, for example, such as a site-directed mutagenesis inducing method. Such mutant proteins are not limited to those intentionally mutated by a known mutant protein producing method, but also include those prepared by isolating and purifying mutant proteins that exist in nature.

Proteins according to the present invention are not particularly limited as long as they are polypeptides consisting of amino acids forming peptide bonds. For example, the proteins may be conjugated proteins with an additional non-peptide structure. Non-limiting examples of such a non-peptide structure include a sugar chain and isoprenoid group.

Further, proteins according to the present invention may include additional peptides. Examples of such additional peptides include various epitopes such as His, Myc, and Flag tagged to proteins of the present invention.

Further, proteins according to the present invention may be obtained by introducing genes according to the present invention (genes encoding proteins of the present invention)

into a host cell and expressing the genes therein. Alternatively, the proteins may be obtained by isolating and purifying from cells or tissues. Further, depending on the expression conditions in the host cell, proteins according to the present invention may be fusion proteins with other proteins. Further, proteins according to the present invention may be chemically synthesized.

(4) Method of obtaining proteins and genes according to the present invention

A method of obtaining (producing) proteins and genes according to the present invention is not particularly limited. The following describes some representative methods.

[Method of obtaining a protein]

As mentioned above, a method of obtaining (producing) proteins of the present invention is not particularly limited. In one method, proteins according to the present invention are simply purified from cells or tissues expressing the proteins. A purification method is not particularly limited either. For example, a cell extract prepared from cells or tissues by a known method is purified by a known method, using a column for example.

Further, proteins according to the present invention may be obtained by a method employing a genetic engineering

technique. In this case, for example, a vector that has incorporated genes of the invention is expressibly introduced into a host cell by a known method, and the proteins obtained by translating the genes in the cell are purified.

5 An expression vector used to introduce foreign genes into a host is suitably selected from a group of expression vectors that have incorporated different types of promoters that become functional in the host and express the genes. A host is also suitably selected from different types of hosts.
10 For the purification of the proteins, different methods are used depending on the type of host or properties of the proteins used. For example, required proteins can be purified relatively easily with use of a tag.

 A method of preparing a mutant protein is not
15 particularly limited either. For example, a mutant protein may be generated by introducing a point mutation in the nucleotide sequence using conventional mutant protein inducing methods, such as a site-directed mutagenesis (see Hashimoto-Gotoh, Gene 152, 271-275 (1995), for example) or
20 PCR. Alternatively, a mutant protein may be generated by a method in which mutant strains are produced by insertion of transposons. Further, a commercially available kit may be used to prepare mutant proteins.

A method of obtaining proteins of the present invention is not limited to the foregoing methods, and a chemical synthesis method may be used. For example, proteins according to the present invention may be synthesized from genes of the present invention, using a cell-free protein synthesis solution.

[Method of obtaining genes]

A method of obtaining (producing) genes of the present invention is not particularly limited either. For example, a method employing differential screening (subtraction cloning) may be used. In this method, direct hybridization is repeated in a test tube according to a method known in the art, so as to concentrate required cDNA (genes of the invention).

The differential screening may be carried out in steps under the conditions normally employed. The resulting clones can then be analyzed in detail by creating a restriction enzyme map and by sequencing the clones. By the analysis, the presence or absence of DNA fragments including gene sequences of the present invention can be confirmed.

In another method of obtaining genes of the present invention, DNA fragments including genes of the present invention are isolated and cloned by a known method. For example, a probe is prepared that hybridizes specific to a

portion of nucleotide sequences of genes according to the present invention, so as to screen the genomic DNA library or cDNA library. The probe is not particularly limited and may have any sequence or length, as long as it can hybridize specific to at least a portion of nucleotide sequences or their complementary sequences of genes according to the present invention.

When a probe sequence is selected from a region well conserved among different species of *Marchantiales*, screening of genomic DNA or cDNA of other species of *Marchantiales* using the probe enables isolation and cloning of genes that encode homologous or analogous molecules functionally similar to proteins of the invention.

Further, in another method of obtaining genes of the present invention, amplifying means such as PCR may be used. For example, primers are prepared from the 5' end and 3' end of a cDNA sequence (or its complementary sequence) of genes according to the present invention. With these primers, PCR is carried out using the genomic DNA (or cDNA) as a template. The PCR amplifies a region of DNA flanked by the primers, thereby producing a large number of DNA fragments including genes of the present invention.

(5) Method of use (usefulness) of genes and proteins

according to the present invention

(5-1) Recombinant expression vector

5 A recombinant expression vector according to the present invention is not particularly limited as long as it includes genes of the present invention described in section (2) above. For example, a recombinant expression vector that has incorporated cDNA may be used. The recombinant expression vector may be prepared using a plasmid, phage, or cosmid as non-limiting examples. Alternatively, the
10 recombinant expression vector may be prepared by a method known in the art.

The type of vector is not particularly limited as long as it is expressed in a host cell. Specifically, such vectors are prepared by introducing genes of the present invention in a
15 plasmid along with promoter sequences that have been suitably selected to ensure gene expression. The promoter sequences depend on the type of host cell.

Various markers may be used to confirm whether genes of the present invention have been introduced in a host cell, or whether the genes have been successfully expressed in the
20 host cell. For example, a marker (a gene lacking in the host cell) is integrated with a carrier, such as a plasmid, together with genes of the present invention, and is introduced into

the host cell as an expression vector. Successful uptake of the genes of the present invention may be confirmed by checking the expression of the marker in the host cell that has incorporated the expression vector. Alternatively, protein
5 according to the present invention may be expressed in the form of fusion proteins in the host cell. For example, proteins according to the present invention may be expressed as fusion proteins with a green fluorescence protein (GFP) derived from *Aequorea victoria*. In this case, the GFP is used as a marker.

10 The host cell is not particularly limited, and various conventionally available cells may be used. Non-limiting examples of such cells include: bacteria such as *Escherichia coli*; yeasts such as *Saccharomyces cerevisiae* or *Schizosaccharomyces pombe*; *Caenorhabditis elegans*; and
15 oocytes of *Xenopus laevis*.

A method of introducing the expression vector into the host cell (method of transformation) is not particularly limited and various conventional methods may be used, including an electroporation method, calcium phosphate method, liposome
20 method, and DEAE dextran method, for example. Further, when proteins of the present invention are transferred and expressed in insects, an expression system using baculovirus may be used.

(5 - 2) Transformants

Transformants according to the present invention are not particularly limited as long as they incorporate genes of the present invention described in section (2) above. As the
5 term is used herein, "transformants" means not only cells, tissues, or organs, but also living organisms themselves.

A method of preparing (producing) transformants is not particularly limited. For example, a host cell may be transformed by introducing a recombinant expression vector
10 described above. The organisms to be transformed are not particularly limited, and may be microorganisms or animals as exemplified above.

Further, transformants according to the present invention are preferably plants into which genes of the
15 present invention are expressibly introduced, or their progeny or vegetatively propagated plants having the same characteristics. Preferably, tissues of these plants also fall within the meaning of "transformants." With these transformant plants, polyunsaturated fatty acids such as
20 arachidonic acid and EPA can be produced at low cost by an environmentally friendly process.

Further, as used herein, "expressibly introduce genes" means that genes are expressibly introduced into a target cell

(host cell), using known genetic engineering (gene manipulation) techniques.

5 The recombinant expression vector used for the transformation of plants is not particularly limited as long as it can express the inserted genes in the plant cell. Examples of such a vector include a vector with a promoter (for example, cauliflower mosaic virus 35S promoter) for constitutively expressing genes in a plant cell, and a vector with a promoter that is inductively activated in response to external stimuli.

10 Here, the plant cells include various types of plant cells, for example, such as cells in a suspension culture, protoplasts, slices of leaves, and calluses.

The recombinant expression vector may be introduced into a plant cell by a method known in the art, for example,

15 such as a polyethylene glycol method, electroporation method, a method using *Agrobacterium*, and a particle gun method. Reproduction of plants from the transformed cells may be carried out by a method known in the art.

For example, there have been established methods of

20 obtaining transformed tobacco, including: a method in which a transformed *Agrobacterium* is used to infect a tobacco leaf disc; a method in which genes are introduced into a protoplast using polyethylene glycol to reproduce plants; a

method in which genes are introduced into a protoplast by an electrical pulse to reproduce plants; and a method in which genes are directly introduced into a cell by a particle gun method to reproduce plants. The present invention can
5 suitably employ any of these methods.

Further, beside *Arabidopsis thaliana*, tobacco is also a model plant of plant cultivation using genetic engineering techniques. Once a transformant tobacco with a high arachidonic acid or EPA content is obtained, it will be
10 possible to obtain such transformants in all other plants. In addition to transformant tobacco, the present invention also provides transformant rice, as will be described later in Examples. Therefore, the invention is able to provide transformants in any type of plant.

For example, there have been established methods of obtaining transformed rice, including: a method in which genes are introduced into a protoplast using polyethylene glycol to reproduce plants; a method in which genes are introduced into a protoplast by an electrical pulse to
15 reproduce plants; and a method in which genes are directly introduced into a cell by a particle gun method to reproduce plants. The present invention can suitably employ any of these methods.
20

With a transformant rice containing an increased level of arachidonic acid or EPA, intake of these and other polyunsaturated fatty acids is possible only by eating the seeds (grains) of the transformant. Therefore, the transformant rice is highly valuable as a food crop, and is highly useful in food industries and agricultures. Further, arachidonic acid or EPA can also be produced in rice bran, chaff, or tiller, which are often wasted. By extracting fatty acids from these parts of plant, they can be efficiently used as a source of health food. They can also be used as food of domestic animals.

Once a transformant plant is obtained that has incorporated genes of the present invention in its genome, progeny of the plant can be obtained by reproducing the plant either sexually or asexually. Further, reproductive materials, for example, such as seeds, fruits, cuttings, tuberous stems, tuberous roots, stumps, callus, and protoplasts may be obtained from the plant, or from its progeny or clones. From these reproductive materials, the plant may be mass produced. The present invention therefore includes plants into which genes of the invention are expressibly introduced, their progeny or vegetatively propagated plants having the same characteristics, tissues of the plants, and reproductive

materials of the plants. Further, the plants, their progeny or vegetatively propagated plants having the same characteristics, and tissues of the plants include plants that are reproduced vegetatively. Vegetative reproduction is also known as vegetative generation or clonal expansion, and is commonly carried out by making a plant or herbaceous cutting. In a test tube, vegetative reproduction of plants may be carried out by redifferentiating plants from such organs as the leaf, stem, or root, or by using a callus. In some plant species, a unique winter bud may form at the tip of a branch, or a succulent axillary bud may be formed. In other cases, flowers may form a propagule, or a tuber may be formed.

Further, the present invention includes plants into which genes of the present invention are expressibly introduced, and whose fatty acid composition is modified by the expression of the genes. The invention also includes their progeny or vegetatively propagated plants having the same characteristics, tissues of the plants, and reproductive materials of the plants. As used herein, "modification of fatty acid composition" means altering of a fatty acid composition of plant by way of transformation. For example, such a change can be induced by introducing genes of the present invention to transform a plant which does not contain

arachidonic acid or EPA in its fatty acid composition. This will change the fatty acid composition of the plant by the production of arachidonic acid and EPA.

(5-3) Fatty acid producing method

5 The present invention includes a producing method of fatty acids, using a plant that has been transformed by genes of the present invention and thereby whose fatty acid composition has been modified, or using tissues of the plant.

10 For example, food oil may be produced from a transformant according to the present invention containing a high level of arachidonic acid or EPA. With the increased level of arachidonic acid or EPA, the value of the product food oil can be increased. Further, various parts of the transformant plant, for example, such as seeds, fruits, cuttings, tuberous
15 stems, and tuberous roots, can be used to supply arachidonic acid- or EPA-containing food with an increased value.

(5-4) Material substance

20 The present invention includes a substance obtained by a fatty acid producing method of the invention. Specifically, the invention includes a material substance which includes at least one compound selected from the group consisting of: γ -linolenic acid, dihomogamma-linolenic acid, arachidonic acid, stearidonic acid, eicosatetraenoic acid, and eicosapentaenoic

acid. As used herein, "material substance" means all substances usable as raw materials for various industrial purposes, including seeds, fruits, cuttings, tuberous stems, and tuberous roots, provided as food.

5 A material substance containing arachidonic acid or EPA may be used to provide health food, film, biodegradable plastic, functional fiber, lubricant, and detergent, for example. The polyunsaturated fatty acids have a unique property of containing more than one double bond within the molecule.
10 Thus, by producing arachidonic acid or EPA in a transformant of the present invention for example, production cost can be reduced. Further, the invention realizes an environmentally friendly producing process.

(5-5) Fatty acid composition modifying method

15 The present invention includes a method of modifying a fatty acid composition using genes of the present invention. For example, with a transformant that has incorporated genes of the present invention as above, a fatty acid composition of the host cell can be modified. A target organism of fatty acid
20 composition modification is not particularly limited. Other than plants, any organism may be used, including animals, microorganisms, and yeasts.

(5-6) Gene detecting instrument

A gene detecting instrument according to the present invention includes at least a portion of a nucleotide sequence, or its complementary sequence, of a gene of the present invention as a probe. The gene detecting instrument of the invention can be used, under various conditions, for the measurement or detection of expression pattern of genes according to the present invention.

An example of a gene detecting instrument according to the present invention is a DNA chip in which a probe that hybridizes specific to genes of the present invention is immobilized on a substrate (carrier). As used herein, the term "DNA chip" generally means a synthetic DNA chip using a synthetic nucleotide as a probe, but the "DNA chip" also means an adhesion DNA microarray that uses a PCR product, such as cDNA, as a probe.

The probe sequence may be determined by a conventional method of specifying a characteristic sequence of cDNA sequences. For example, a SAGE (Serial Analysis of Gene Expression) method, as described in Science 276:1268, 1997; Cell 88: 243, 1997; Science 270: 484, 1995; Nature 389: 300, 1997; US patent No. 5,695, 937 may be used.

The DNA chip may be made by a conventional method. For example, when a synthetic oligonucleotide is used, it may

be synthesized on a substrate by a combination of photolithography and solid phase DNA synthesis technique. On the other hand, when the oligonucleotide is cDNA, it is stuck on a substrate using an array device.

5 Further, as in common DNA chips, the accuracy of gene detection can be improved by placing a perfect-match probe (oligonucleotide) with a mismatch probe that has been prepared by substituting a single nucleotide of the perfect-match probe. Further, in order to detect different
10 genes simultaneously, a DNA chip may be prepared in which different types of oligonucleotides are immobilized on a single substrate.

 A gene detecting instrument of the present invention is not just limited to the DNA chip as exemplified above, as long
15 as it uses at least a portion of a nucleotide sequence, or its complementary sequence, of a gene of the present invention as a probe.

(5-7) Antibody

 An antibody according to the present invention is a
20 polyclonal or monoclonal antibody obtained by a method known in the art, using proteins of the invention, or fragments of the proteins or peptides as an antigen. Examples of the conventional method include Harlow et al.; Antibodies:

A laboratory manual (Cold Spring Harbor Laboratory, New York (1988), and Iwasaki et al.; Monoclonal antibody, hybridoma and ELIZA, Kodansha (1991). The antibody may be used in the detection and/or measurement of a protein according to the present invention.

(5-8) Screening method

A screening method according to the present invention uses proteins of the present invention to screen for genes or substances that regulate the proteins. A screening method of the invention is not particularly limited, and a variety of conventional methods that find the presence or absence of bonding or dissociation between substances may be used. For example, substances that facilitate the activities of proteins according to the present invention ($\Delta 6$ desaturase activity, $\Delta 6$ chain elongase activity, and/or $\Delta 5$ desaturase activity) may be screened.

The present invention also includes genes or proteins obtained by such a screening method.

While the invention is susceptible to various modifications and alternative forms, a specific embodiment thereof will be described below in more detail by way of Examples with reference to the attached drawings. It should be understood, however, that it is not intended to limit the

invention to the particular forms disclosed, but on the contrary, the invention is to cover all modifications, equivalents, and alternatives falling within the scope of the invention as defined in the appended claims.

5 [EXAMPLES]

In the following Examples, experimental methods, unless otherwise specified, are based on the method described in Molecular Cloning (Sambrook et.al. Cold Spring Harbour Laboratory Press, 1989).

10 [Example 1: Isolation of *Marchantia polymorpha*-derived $\Delta 6$ desaturase gene]

A comparison of amino acid sequences of cloned $\Delta 6$ desaturases has confirmed that the amino acid sequences Trp-Trp-Lys-(Glu/Asp)-Lys-His-Asn (SEQ ID NO: 37) and
15 Trp-Phe-Thr-Gly-Gly-Leu-Asn (SEQ ID NO: 38) were conserved. To isolate a *Marchantia polymorpha*-derived $\Delta 6$ desaturase gene, the following degenerate primers encoding the above amino acid sequences were used:

d $\Delta 6$ DES-F:

20 5'-TG GTG GAA(A/G)GA(A/G/T/C)AA(A/G)CA(T/C)AA-3'
(SEQ ID NO: 7); and

d $\Delta 6$ DES-R:

5'-(A/G)TTIA(A/G)IC CICCIGT(A/G)AACCA-3' (SEQ ID NO:

8).

("I" denotes inosine, and more than one nucleotide exist in parentheses.)

5 A thallus of E-line *Marchantia polymorpha* (see Transgenic Res. 9, p179, 2000) was used as a sample. Isolation of poly(A)⁺ RNA from the thallus was carried out in accordance with the method described in Biosci. Biotechnol. Biochem. 67, p605, 2003; Biosci. Biotechnol. Biochem.67, p1667, 2003. 1.5 µl of isolated poly(A)⁺ RNA was
10 reverse-transcribed to cDNA using a Ready-To-Go T-primed First Strand kit (Amersham). PCR was carried out with about 10 ng of the cDNA as a template, using the foregoing primers (dΔ6DES-F and dΔ6DES-R) and 0.5 U of enzyme (Takara Ex Taq, Takara), by a method recommended by the manufacturer.
15 Using a GeneAmp PCR system 9700 (PE Applied Biosystems), the PCR was carried out with 20 µl of a reaction solution under the following conditions: 94°C for 2 minutes, followed by 35 cycles of reaction at 94°C for 1 minute, 45°C for 1.5 minutes, and 72°C for 2 minutes, and cooling down to 4°C.

20 The resulting PCR product was electrophoresed on a 1% (w/v) agarose gel, and amplified fragments having a size expected from a known amino acid sequence of a conventional Δ6 desaturase was collected from the gel using a Prep-A Gene

(Bio-rad). The collected fragments were ligated to a pT7Blue Vector (Takara) and transformed into Escherichia coli Electro-max DH10B cells (Invitrogen, Carlsbad, CA).

5 Nucleotide sequences of all clones obtained by a BigDye Terminator Cycle Sequencing kit (Applied Biosystems) and an automated sequencer ABI PRISM 377 (Applied Biosystems) were determined, and the clones were screened for a target cDNA sequence.

10 Further, to obtain a full-length cDNA sequence, 5'-RACE and 3'-RACE were carried out by a method recommended by the manufacturer, using a 5'-RACE System for Rapid Amplification of cDNA Ends Version 2.0 (Invitrogen), a Ready-To-Go T-primed First Strand kit (Amersham), and the following primers:

15 MpDES6-02R:

5'-AAGTTGCCTTCGATGTTTCTGG-3' (SEQ ID NO: 9); and

MpDES6-01F:

5'-GCTCGCCTGGAGCAAGGAAATC-3' (SEQ ID NO: 10).

20 As a result, one type of candidate homologue gene was isolated as an MpDES6 gene. The length of cDNA (not including a poly(A) portion) of the isolated MpDES6 gene was 2,522 bp, and an amino acid sequence encoded by the MpDES6 gene was estimated to have 481 residues. The

nucleotide sequence and amino acid sequence of the MpDES6 gene are represented by SEQ ID NO: 1 and SEQ ID NO: 2, respectively.

5 A comparison between the estimated amino acid sequence of MpDES6 cDNA and an amino acid sequence of $\Delta 6$ desaturase from *Physcomitrella patens* found only 47.5% identity.

[Example 2: Isolation of *Marchantia polymorpha*-derived $\Delta 6$ chain elongase gene]

10 A comparison of amino acid sequences of cloned $\Delta 6$ chain elongases has confirmed that the amino acid sequences Val-Glu-Phe-Met-Asp-Thr-Val (SEQ ID NO: 39) and Lys-Tyr-Leu-Phe-Trp-Gly-Arg (SEQ ID NO: 40) were conserved. To isolate a *Marchantia polymorpha*-derived $\Delta 6$ chain elongase
15 gene, the following degenerate primers coding for the above amino acid sequences were used:

d $\Delta 6$ ELO-F:

5'-GTIGA(A/G)TT(T/C)ATGGA(T/C)ACIGT-3' (SEQ ID NO:
11); and

20 d $\Delta 6$ ELO-R:

5'-C(G/T)ICCCCA(A/G)AAIA(A/G)(A/G)TA(T/C)TT-3' (SEQ
ID NO: 12).

PCR was carried out using the these primers (d $\Delta 6$ ELO-F

and dΔ6ELO-R), and the resulting DNA fragments were subcloned. Nucleotide sequences of the clones were determined, and a full-length cDNA was obtained for clones that had a target cDNA sequence, using the following primers:

5 MpELO1-02R:

5'-GCGAGCTTTCTCGTTCTTTCCC-3' (SEQ ID NO: 13);

and

MpELO1-01F:

5'-TATGATTTTGAAGCGCAACACG-3' (SEQ ID NO: 14).

10 Note that, the materials and methods for the experiment were the same as for Example 1.

As a result, one type of candidate homologue gene was isolated as an MpELO1 gene. The length of cDNA (not including a poly(A) portion) of the isolated MpELO1 gene was
15 1,559 bp, and an amino acid sequence encoded by the MpDES1 gene was estimated to have 290 residues. The nucleotide sequence and amino acid sequence of the MpDES1 gene were represented by SEQ ID NO: 3 and SEQ ID NO: 4, respectively.

20 A comparison between the estimated amino acid sequence of MpELO1 cDNA and an amino acid sequence of Δ6 chain elongase from *Physcomitrella patens* found 62.7% identity.

[Example 3: Isolation of *Marchantia polymorpha*-derived $\Delta 5$ desaturase gene]

The $\Delta 5$ desaturases of other species have a cytochrome b5 domain at their N-terminus. From this, it was speculated that a *Marchantia polymorpha*-derived $\Delta 5$ desaturase gene belongs to a cytochrome b5-domain fusion desaturase gene family, as does the $\Delta 6$ desaturase gene. However, in *Phaeodactylum tricornutum* and fungi, the homology between the $\Delta 5$ desaturase and $\Delta 6$ desaturase is very poor at an amino acid level. As such, amino acid sequences of the $\Delta 5$ desaturase and $\Delta 6$ desaturase were compared in a filamentous fungus (*M. alpina*). The comparison found local presence a contiguous conserved sequence of 4 to 5 residues, which is at least required for the designing of degenerate primers. Surprisingly, the amino acid sequences were more conserved between the $\Delta 5$ desaturase and $\Delta 6$ desaturase of the same species than between $\Delta 5$ desaturases obtained from different species. This suggests the presence of a species-specific conserved sequence in the cytochrome b5-domain fusion desaturase gene. To investigate on this, the nucleotide sequences of the MpDES6 and the MpDES of an unknown function, described in Genetics 159, p981, 2001, were compared. As a result, it was found that two amino acid

sequences: (I(E/N)(G/D)KVYDV (SEQ ID NO: 41) and DPDI(Q/D)(Y/T)(M/V)P (SEQ ID NO: 42)) were conserved. Sequences of degenerate primers corresponding to the respective amino acid sequences are as follows:

5 dΔ5DES-F:

5'-AT(A/T/C)(A/G)AIG(A/G)IAA(A/G)TITA(T/C)GA(T/C)GT
-3' (SEQ ID NO: 15); and

dΔ5DES-R:

5'-GGIA(T/C)I(G/T)(A/T)IT(G/C)(A/G/T)AT(A/G)TCIGG(A
10 /G)TC-3' (SEQ ID NO: 16).

PCR was carried out using these primers (dΔ5DES-F and dΔ5DES-R), and the resulting DNA fragments were subcloned. Nucleotide sequences of the clones were determined, and a full-length cDNA was obtained for clones that had a target
15 cDNA sequence, using the following primers:

MpDES5-02R:

5'-GTGTGTACGATCCGTGGTTACC-3' (SEQ ID NO: 17);
and

MpDES5-01F:

20 5'-AAGGCGGGACAGGATTCAACAC-3' (SEQ ID NO: 18).

Note that, the materials and methods for the experiment were the same as for Example 1.

From the cDNA, clones c1 and c2 of different lengths

(c1: 2,427 bp; c2: 2,285 bp) were isolated as candidates for the *Marchantia polymorpha*-derived $\Delta 5$ desaturase. By comparing the nucleotide sequences of the clones c1 and c2, it was found that alternative splicing had occurred in a 5' non-coding region. The alternative splicing did not change the reading frame, and both clones c1 and c2 coded for 484 amino acids (SEQ ID NO: 6). The clone c1 of 2,427 bp was used as a MpDES5 gene (SEQ ID NO: 5) in the following Examples.

A comparison of an estimated amino acid sequence of MpDES5 cDNA with an amino acid sequence of the $\Delta 5$ desaturase of a filamentous fungus (*M. alpina*) found 31.4% identity. No comparison was made for the $\Delta 5$ desaturase of *Physcomitrella patens*, which is closely related to *Marchantia polymorpha*, because no sequence information is available for the $\Delta 5$ desaturase of this particular organism.

[Example 4: Functional analysis using methylotrophic yeast (*Pichia pastoris*)]

To examine functions of the respective cDNAs of the MpDES6, MpELO1, and MpDES5, a construct in which an ORF was placed downstream of a methanol-inducible promoter AOX1 was prepared for each gene. The constructs were introduced into methylotrophic yeast (*Pichia pastoris*) to analyze their fatty acid compositions. The ORFs of cDNA

nucleotide sequences of the MpDES6, MpELO1, and MpDES5 were PCR-amplified using the following primers.

(Primers for the amplification of MpDES6 ORF)

MpD6-17F:

5 5'-GGAATTCGCGATGGCCTCGTCCACCACCAC-3' (SEQ ID NO: 19); and

MpD6-18F:

5'-GGAATTCTACTTTCGCAGCGTATGCTACC-3' (SEQ ID NO: 20).

10 (Primers for the amplification of MpELO1ORF)

MpD6ELO1-15F:

5'-GGAATTCGCGATGGAGGCGTACGAGATGG-3' (SEQ ID NO: 21); and

MpD6ELO1-16F:

15 5'-GGAATTCTTCTGCCTTTTGCTCTTGATC-3' (SEQ ID NO: 22).

(Primers for the amplification of MpDES5 ORF)

MpD5-11F:

20 5'-GTTGAAATTCGACAGTTATGCCGCCACACGC-3' (SEQ ID NO: 23); and

MpD5-12R:

5'-GTTGAAATTCAGGCCCAAAGCATGCTGTCAC-3' (SEQ ID NO: 24).

These primers contained EcoRI recognition sequences (underlined) and were used in the following cloning process. Further, PCR was carried out using 0.5 U of Pyrobest DNA polymerase (Takara) with 20 µl of reaction solution, in accordance with the method recommended by the manufacturer. The reaction condition was as follows: 94°C for 2 minutes, followed by 25 cycles of reaction at 94°C for 1 minute, 57°C for 1 minute, and 72°C for 1 minute, and cooling down to 4°C. Each of the resulting ORF fragments was digested with EcoRI, gel purified by the method described in Example 1, and ligated in the sense direction to an EcoRI site downstream of a methanol-inducible promoter 5'AOX1 in a methylotrophic yeast expression vector pPICZA (Marker: zeocin-resistant gene, Invitrogen).

In order to obtain transformants, expression constructs and a pPICZA vector as a control were introduced into a PPY1-line of methylotrophic yeast using a Pichia EasyComp kit (Invitrogen), using a zeocin-resistant gene as a marker. Note that, the methylotrophic yeast can synthesize linoleic acid and α -linolenic acid, which are substrates of the $\Delta 6$ desaturase, but cannot synthesize other precursors of arachidonic acid or EPA.

To express the introduced genes in the transformants,

the transformants were first cultured until OD (600 nm) became 0.5 in a minimal medium containing 1.0% glycerol as a sole carbon source. The transformants were then cultured at 30°C for three days in a minimal medium containing 0.5% methanol as a sole carbon source, until saturation was reached. Here, an EasySelect Pichia Expression Kit (Invitrogen) was used according to the method recommended by the kit. Thereafter, fatty acid compositions of the respective transformants were measured using a GC-MS and according to a known method (Biosci. Biotechnol. Biochem. 67, p605, 2003).

In an MpDES6 gene-expressing transformant, the products of the $\Delta 6$ desaturase reaction, g-linolenic acid and stearidonic acid, were contained in 7.4% and 0.7%, respectively, with respect to the total fatty acids. In a pPICZA vector-introduced yeast used as a control, γ -linolenic acid and stearidonic acid were not detected. Thus, it was shown that the MpDES6 encoded the $\Delta 6$ desaturase.

In an MpELO1 gene-expressing transformant, 14.1% of the total fatty acids was dihomo- γ -linolenic acid when γ -linolenic acid was added. On the other hand, 1.5% of the total fatty acids was eicosatetraenoic acid when stearidonic acid was added. In a pPICZA vector-introduced yeast used as

a control, dihomog-linolenic acid or eicosatetraenoic acid was not detected. Thus, it was shown that the MpELO1 encoded the $\Delta 6$ chain elongase.

In an MpDES5 gene-expressing transformant, 1.1% of the total fatty acids was arachidonic acid when dihomog-linolenic acid was added. On the other hand, 0.1% of the total fatty acids was eicosapentaenoic acid (EPA) when stearidonic acid was added. In a pPICZA vector-introduced yeast used as a control, arachidonic acid or eicosapentaenoic acid was not detected. Thus, it was shown that the MpDES5 encoded the $\Delta 5$ desaturase.

It was therefore confirmed that *Marchantia polymorpha* can be used to obtain MpDES6, MpELO1, and MpDES5, which are genes that encode the $\Delta 6$ desaturase, $\Delta 6$ chain elongase, and $\Delta 5$ desaturase, respectively.

[Example 5: Reconstruction of *Marchantia polymorpha* polyunsaturated fatty acid biosynthesis system in a methylotrophic yeast (*P. pastoris*)]

To co-express the MpDES6, MpELO1, and MpDES5, EcoRI-digested amplified ORF fragments of MpELO1 and MpDES5 prepared in Example 4 were ligated to a methylotrophic yeast-expression vector pPIC3K (Marker: HIS4 gene, Invitrogen) and a methylotrophic yeast-expression

vector PIC6A (Marker: blasticidin-resistant gene, Invitrogen), respectively. In each vector, the ligation was made in the sense direction at the EcoRI site downstream of a 5'AOX1 promoter. For the MpDES6, the expression vector prepared in Example 4 was used. Hereinafter, the expression vectors for the MpDES6, MpELO1, and MpDES5 are referred to as pPICZA-MpDES6 vector, pPIC3K-MpELO1 vector, and pPIC6A-MpDES5 vector, respectively.

The pPICZA-MpDES6 vector was transferred into a methylotrophic yeast PPY12 line (his4, arg4) having the same fatty acid composition as the methylotrophic yeast PPY1 used in Example 4. As a control, a pPICZA vector was also transferred. Transformants were obtained using a zeocin-resistance marker. Then, the pPIC3K-MpELO1 vector was introduced into the transformant that has incorporated the pPICZA-MpDES6 in its genome and the transformant that has incorporated the pPICZA in its genome. The pPIC3K vector was also introduced as a control into the transformants in the same manner. Transformants were obtained using the histidine synthesizing ability as a marker. Finally, the pPIC6A-MpDES5 vector was introduced into the transformant that has incorporated the pPICZA-MpDES6 and pPIC3K-MpELO1 in its genome, and to the transformant that

has incorporated the pPICZA and pPIC3K in its genome. The pPIC6A vector was also introduced as a control into the transformants in the same manner. Transformants were obtained using the blasticidin resistance as a marker.

5 Using the transformants that have incorporated two or three kinds of genes, an experiment was conducted to reconstruct the arachidonic acid/EPA biosynthesis system of *Marchantia polymorpha*. First, using the transformants that have incorporated the two types of genes (MpDES6 and
10 MpELO1), an MpDES6 protein and an MpELO1 protein were co-expressed in the methylotrophic yeasts. As a result, g-linolenic acid and stearidonic acid, which are the products of $\Delta 6$ desaturation, were contained in 2.9% and 0.4%, respectively, with respect to the total fatty acids, whereas
15 dihomo-g-linolenic acid and eicosatetraenoic acid, which are produced by the chain elongation of the g-linolenic acid and stearidonic acid, respectively, were contained in 2.8% and 0.2%, respectively, with respect to the total fatty acids. In the controls, these fatty acids were not detected. In the
20 transformants that have incorporated three types of genes (MpDES6, MpELO1, and MpDES5), production of arachidonic acid (0.1% in the total fatty acids) and eicosapentaenoic acid (EPA, 0.03% in the total fatty acids) was confirmed, in

addition to the g-linolenic acid, stearidonic acid, dihomog-linolenic acid, and eicosatetraenoic acid, which were contained in 2.8%, 0.5%, 1.5%, and 0.1%, respectively, with respect to the total fatty acids. In the controls, these fatty acids were not detected. This result showed that reconstruction of polyunsaturated fatty acid biosynthesis system is indeed possible in organisms other than *Marchantia polymorpha*, by expressing *Marchantia polymorpha*-derived $\Delta 6$ desaturase gene, $\Delta 6$ chain elongase gene, and $\Delta 5$ desaturase gene therein.

[Example 6: Construction of a vector for rice, and transfer of the vector into rice]

To express the MpDES6 gene, MpELO1 gene, and MpDES5 gene in rice, expression constructs were prepared in the following steps (i) to (iv). Figure 1 shows the procedure.

In PCR using primers that were designed between a cauliflower mosaic virus (CaMV) 35S promoter and a NOS terminator of pBI221 (TOYOBO), an expression vector p35S-NOS not including a β -Glucuronidase (GUS) gene portion was prepared.

Namely, the following primers were used in PCR:

MK001(F):

5'-CGGGATCCTCTCCTGGCGCACCATCGTC-3' (SEQ ID

NO: 25); and

MK002(R):

5'-GGGGTACCAACGCGCTTTCCCACCAACG-3' (SEQ ID
NO: 26).

5 Note that, the primer MK001(F) contained a BamHI
recognition sequence (underlined) and was annealed to the 3'
end of the GUS gene. The primer MK002(R) was annealed to
the 5' end of the GUS gene. (BamHI site is upstream of the
annealed site.) The PCR was carried out with 50 µl of reaction
10 solution, using 0.5 U of Pyrobest DNA polymerase (Takara) by
the method recommended by the manufacturer. The reaction
conditions were as follows: 96°C for 5 minutes, followed by 30
cycles of reaction at 94°C for 30 seconds and 68°C for 4
minutes, and cooling down to 4°C. The resulting ORF
15 fragments were digested with BamHI, gel purified by the
method described in Example 1, and were self-ligated.

(ii) Next, the ORFs of the MpDES6 gene, MpELO1 gene,
and MpDES5 gene were ligated to the XbaI site of p35S-NOS.
For the amplification of ORFs, the following primers
20 containing an XbaI recognition sequence (underlined) were
used.

(Primers for the amplification of MpDES6 ORF):

MpD6-21F:

5'-GCTCTAGAGCGATGGCCTCGTCCACCACC-3' (SEQ ID NO: 27); and

MpD6-11R:

5'-GCTCTAGACTATACTTTCGCAGCGTATGC-3' (SEQ ID NO: 28).

(Primers for the amplification of MpELO1 ORF):

MpD6ELO1-18F:

5'-GCTCTAGAGCGATGGAGGCGTACGAGATGG-3' (SEQ ID NO: 29); and

MpD6ELO1-13R:

5'-GCTCTAGATTATTCTGCCTTTTGTCTC-3' (SEQ ID NO: 30).

(Primers for the amplification of MpDES5 ORF):

MpD5 22F:

5'-GCTCTAGAGACAGTTATGCCGCCACACGC-3' (SEQ ID NO: 31); and

MpD5 23R:

5'-GCTCTAGAAGGCCCAAAGCATGCTGTCAC-3' (SEQ ID NO: 32).

The PCR was carried out with 20 µl of reaction solution, using 0.5 U of Pyrobest DNA polymerase (Takara) by the method recommended by the manufacturer. The reaction conditions were as follows: 94°C for 2 minutes, followed by 25

cycles of reaction at 94°C for 1 minute, 57°C for 1 minute,
and 72°C for 1 minute, and cooling down to 4°C. The
resulting ORF fragments were digested with XbaI, gel-purified
by the method described in Example 1, and were used for
cloning.

(iii) By taking advantage of the fact that all of the
resulting gene-expression constructs (respectively represented
by p35S-MpDES6, p35S-MpELO1, and p35S-MpDES5) had a
PstI site at the 5' end of the CaMV35S promoter and an EcoRI
site at the 3' end of the NOS terminator, expression cassettes
for these three genes were ligated to one another. First, PCR
was carried out using the primers below, and a p35S-MpDES5
as a template, so as to amplify an expression cassette portion
of the MpDES5 gene. The amplified fragment was then cloned
into the PstI site at the 5' end of the CaMV35S promoter of
the p35S-MpDES (see Figure 1).

(Primers for the amplification of MpDES5-gene
expression cassette)

M13R:

5'-CAGGAAACAGCTATGACC-3' (SEQ ID NO: 33); and

NOS-R4-PST:

5'-AAACTGCAGATTCCCGATCTAGTAACATAG-3' (SEQ ID
NO: 34).

Note that, the M13R primer was annealed to a vector sequence upstream of the CaMV35S promoter. Further, the NOS-R4-PST primer contained a PstI recognition sequence (underlined) and was annealed to the 3' end of the NOS terminator. The EcoRI site at the 3' end of the NOS terminator was not contained.

The PCR was carried out with 20 µl of reaction solution, using 0.5 U of Pyrobest DNA polymerase (Takara) by the method recommended by the manufacturer. The reaction conditions were as follows: 94°C for 2 minutes, followed by 25 cycles of reaction at 94°C for 1 minute, 57°C for 1 minute, and 72°C for 1 minute, and cooling down to 4°C. The resulting DNA fragments were digested with PstI, gel-purified by the method described in Example 1, and cloned into the PstI site of the plasmid (p35S-MpDES6) containing the MpDES6-gene expression cassette.

(iv) To the resulting construct in which the expression cassettes of the MpDES5 gene and MpDES6 gene were ligated (represented by "p35S-MpDES5/35S-MpDES6"), an expression cassette of the MpELO1 gene was further ligated. PCR was carried out using the primers below, and a p35S-MpELO1 as a template, so as to amplify an expression cassette portion of the MpELO1 gene. The amplified fragment was then cloned

into the EcoRI site at the 3' end of the NOS terminator in the MpDES6-gene expression cassette.

(Primers for the amplification of MpELO1-gene expression cassette)

5 35S-F3-EI:

5'-CCGGAATTCGCATGCCTGCAGGTCCCCAGA-3' (SEQ ID NO: 35); and

M13F:

5'-TGTAACGACGGCCAGT-3' (SEQ ID NO: 36).

10 Note that, the 35S-F3-EI primer contained an EcoRI recognition sequence (underlined) and was annealed to the 5' end of the CaMV35S promoter. Further, the M13F primer was annealed to a vector sequence downstream of the NOS terminator.

15 The PCR was carried out with 20 µl of reaction solution, using 0.5 U of Pyrobest DNA polymerase (Takara) by the method recommended by the manufacturer. The reaction conditions were as follows: 94°C for 2 minutes, followed by 25 cycles of reaction at 94°C for 1 minute, 57°C for 1 minute,
20 and 72°C for 1 minute, and cooling down to 4°C. The resulting DNA fragments were digested with EcoRI, gel-purified by the method described in Example 1, and cloned into the EcoRI site of the construct

(p35S-MpDES5/35S-MpDES6) in which the MpDES5-gene expression cassette and the MpDES6-gene expression cassette were ligated.

5 By these procedure, an expression construct (p35S-MpDES5/35S-MpDES6/p35S-MpELO1) was prepared in which the three genes-expression cassettes of MpDES5, MpDES6, and MpELO1 were ligated in this order.

10 The construct so obtained was introduced into rice, together with a plasmid having bialaphos as a selection marker, using a particle gun by a known method (Genes Genet. Syst. 73, p219, 1998). As a result, a transformed rice was obtained.

15 [Example 7: Reconstruction of *Marchantia polymorpha* polyunsaturated fatty acid synthesis system in tobacco (*N. tabacum* SR-1)]

This Example confirmed that the foregoing *Marchantia polymorpha*-derived unsaturated fatty acid synthetase genes, i.e. the MpDES6 gene, MpDES5 gene, and MpELO gene were indeed well functional in plants.

20 More specifically, by introducing the MpDES6 gene, MpDES5 gene, and MpELO gene into tobacco, production of arachidonic acid and other fatty acids were confirmed. For comparison, a tobacco was prepared into which filamentous

fungus (*M. alpina*)-derived $\Delta 6$ desaturase gene (MaDES6), $\Delta 5$ desaturase gene (MaDES5), and $\Delta 6$ fatty-acid-chain elongase (MaELO) were introduced.

5 (i) Construction of a vector (pSPB1519) containing filamentous fungus-derived genes

The pE2113 (Mitsuhara et al. Plant Cell Physiol. 37, 45-59 1996) has a cauliflower mosaic virus 35S (E1235S) promoter, having repeating enhancer sequences, and a nopaline synthase (nos) terminator.

10 The pE2113 was digested with SnaBI and then ligated to an XhoI linker (TAKARA) to obtain a plasmid. The resulting plasmid was digested with SacI, blunted, and ligated to a BamHI linker (TAKARA) to obtain pUE7. Of the DNA fragments obtained by the digestion of pUE7 with HindIII and EcoRI, a
15 fragment having an E1235S promoter was ligated to a plant-transformation binary vector pBINPLUS (van Engelen et al. Transgenic research 4, p288, 1995) digested with HindIII and EcoRI. As a result, pSPB505 was obtained.

20 Meanwhile, a plasmid pMLD101 containing the MaDES6 gene was digested with XhoI followed by partial digestion with BamHI, so as to obtain an about 1.6 kb DNA fragment. The DNA fragment so obtained was ligated to a DNA fragment of a binary vector obtained by the digestion of pSPB505 with XhoI

and BamHI. As a result, pSPB559 was obtained.

The pUCAP (van Engelen et al. Transgenic research 4, p288, 1995) was digested with AscI, blunted, and ligated to a PacI linker to obtain pUCAPP.

5 The pE2113 was digested with SnaBI and ligated to a BamHI linker (TAKARA) to obtain pUE6. This pUE6 was digested with SacI, blunted, and ligated to a SalI linker (TAKARA) to obtain pUE8. Of the DNA fragments obtained by the digestion of pUE8 with HindIII and EcoRI, a fragment
10 having an El235S promoter was inserted into the HindIII-EcoRI site of pUCAPP. A DNA fragment obtained by the digestion of this plasmid with BamHI and SalI was ligated to a DNA fragment obtained by the digestion of cDNA of the MaELO gene with BamHI and XhoI, so as to obtain pSPB1130.
15 The pSPB1130 was digested with PacI, and the resulting DNA fragment of about 2.3 kb was inserted into a PacI site of pBINPLUS. A plasmid having the same transcription direction for the MaELO gene and the nptII gene on the pBINPLUS were selected as pSPB1157P.

20 Further, the pSPB599 was digested with PacI, blunted, and an AscI linker was inserted to prepare pSPB599A. The pSPB599A was digested with AscI, and a DNA fragment containing the MaDES6 gene, obtained from the digestion of

pSPB599A with *AscI*, was inserted into the *AscI* site of pSPB1157P to obtain pSPB1157.

An about 1.3 kb DNA fragment obtained from the digestion of pCGP1364 (Plant Cell Physiol. 36, p1023, 1995) with *HindIII* and *SacII* was ligated to an about 2.9 kb DNA fragment obtained by digesting pCGP1364 with *PstI*, blunting it, and digesting it with *SacII*. These DNA fragments were further ligated to an about 2.7 kb DNA fragment obtained by digesting pUCAPA with *SacI*, blunting it, and digesting it with *HindIII*. As a result, pSPB184 was obtained.

Meanwhile, from a pCRII vector into which the MaDES5 gene was subcloned, a DNA fragment containing the MaDES5 gene was excised by digesting with *XbaI* and *KpnI*. The resulting DNA fragment was ligated to a DNA fragment obtained by the digestion of the pSPB184 with *XbaI* and *KpnI*, so as to obtain pSPB1519A. A DNA fragment obtained by digestion of the pSPB1519A with *AscI* was inserted into the *AscI* site of pSPB1157 to obtain pSPB1519. The pSPB1519 was digested with *AscI* and inserted into the *AscI* site of pSPB1157 to obtain pSPB1519. The MaDES6 gene, MaDES5 gene, and MaELO gene were transcribed in the same direction on the plasmid pSPB1519, and were controlled by the same constitutive promoter.

(ii) Construction of *Marchantia polymorpha*-derived gene vector (pSPB2368)

The pUCAP (van Engelen et al. Transgenic Research 4, 288-290, 1995) was digested with *AscI*, ligated to a *SgfI* linker. By further digesting it with *PacI* followed by ligation to a *FseI* linker, pUCSAPF was obtained. In the same manner, InpBINPLUS was processed to obtain pBINSAPF.

In addition, the pUC19 was digested with *HindIII* and ligated to a *PacI* linker. By further digesting it with *EcoRI* followed by ligation to a *FseI* linker, pUCPF was obtained as a subcloning vector. Further, the pUC19 was digested with *HindIII* and ligated to a *SgfI* linker. By further digesting it with *EcoRI* followed by ligation to an *AscI* linker, pUCSA was obtained. A vector in which El235S was inserted into the *HindIII*-*XbaI* site of pUCSAPF, and in which a mannopin synthetase (*mas*) gene terminator was inserted into the *SacI*-*EcoRI* site of pUCSAPF was digested with *XbaI* and *SacI* and blunted to obtain pSPB2353A. To a blunt end of pSPB2353A, a DNA fragment containing the MaDES6 gene which was excised from the p35S-MpDES6 with *XbaI* and blunted was ligated. As a result, pSPB2353 was obtained.

A vector in which El235S was inserted into the *HindIII*-*XbaI* site of pUCSA, and in which a mannopin

synthetase (mas) gene terminator was inserted into the
SacI-EcoRI of pUCSA was digested with XbaI and SacI to
obtain pSPB2355A.

5 Meanwhile, using the p35S-MpELO1 as a template, PCR
was carried out using the following primers:

XbaMpELOf:

5'-AGTCTCTAGAGCGATGGAGGCGTACG-3' (SEQ ID NO:
43); and

SacMpELOr:

10 5'-CAGTGAGCTCGGTGTCTTATTCTGCC-3' (SEQ ID NO:
44).

PCR was run using a highly accurate KOD-plus-DNA
polymerase (Toyobo) as an enzyme. The reaction was carried
out at a maintained temperature of 94°C for two minutes,
15 followed by 25 cycles of reaction at 94°C for 15 seconds and
at 68°C for 1 to 3 minutes. An MpELO DNA fragment so
prepared was digested with XbaI and SacI, and was ligated to
the pSPB2355A to obtain pSPB2355. Further, a DNA fragment
obtained by the digestion of pSPB2355 with SgfI and AscI was
20 ligated to pSPB2353 digested with SgfI and AscI. As a result,
pSPB2361 was obtained.

A vector in which El235S was inserted into the
HindIII-XbaI site of pUCPF, and in which a mannopin

synthetase (mas) gene terminator was inserted into the SacI-EcoRI site of pUCPF was digested with XbaI and SacI to obtain pSPB2352A.

5 Meanwhile, using the p35S-MpDES5 as a template, PCR was carried out using the following primers:

XbaMpD5f:

5'-AGCTTCTAGAGCCATGCCGCCACACGCCC-3'(SEQ ID NO: 45); and

SacMpD5r:

10 5'-CAGTGAGCTCTCAGCCATCCAGTCGT-3'(SEQ ID NO: 46).

The PCR conditions were the same.

An MpD5 DNA fragment prepared by the PCR was digested with XbaI and SacI and ligated to pSPB2352A to
15 obtain pSPB2352.

A DNA fragment obtained by the digestion of pBINSAPF with PacI and FseI was ligated to a DNA fragment containing the MpDES5 gene which was excised from pSPB2352 with PacI and FseI. As a result, pSPB2368A was obtained.
20 Further, pSPB2368A was digested with SgfI and PacI and ligated to a DNA fragment containing the MpDES6 and MpELO genes which were excised from pSPB2361 with SgfI and PacI. As a result, pSPB2368 was obtained. The MpDES6 gene,

MpDES5 gene, and MpELO gene were transcribed in the same direction on the plasmid pSPB2368, and were controlled by the same constitutive promoter.

(iii) Gene introduction into tobacco

5 Next, according to a known method (Plant J. 5, 81, 1994), *Agrobacterium tumefaciens* (strain: Agl0 (Lazo et al. 1991, Biotechnology 9: 963-967)) was transformed using pSPB2368 or pSPB1519. The transformed *Agrobacterium* having pSPB2368 or pSPB1519 was used to infect a tobacco leaf disk.
10 From the transgenic tobacco leaf so obtained, RNA was extracted using a RNeasy Plant Mini Kit (Qiagen), and a line expressing the introduced gene was selected by RT-PCR using an ordinary method.

15 From the tobacco leaf that has incorporated the pSPB1519 containing the filamentous fungus-derived enzyme gene (pSPB1519-transformed tobacco), and from the tobacco leaf that has incorporated the pSPB2368 containing the *Marchantia polymorpha*-derived enzyme gene (pSPB2368-transformed tobacco), lipids were extracted
20 according to known methods (Yasuhiko FUJINO, "Seibutsu-Kagaku Jikken-ho (Method of Biochemical Experiment) 9", Gakkai Shuppan Center (1978); Akihiro YAMADA, "Seibutsu-Kagaku Jikken-ho (Method of Biochemical

Experiment) 24", Gakkai Shuppan Center (1989)). The lipids were analyzed by gas chromatography (Hewlett Packard, HP-6800). The result of analysis is shown in Table 1.

5 Note that, the same analysis was carried out using, as a control, a tobacco leaf into which no gene was introduced.

[Table 1]

	Contro l (%)	Control (mg/gFW	pSPB236 8 (%)	pSPB236 8	pSPB151 9 (%)
Linoleic acid	9.55	1.17	1.37	0.2	9.51
α -linolenic acid	49.99	6.12	17.83	2.58	39.24
γ -linolenic acid	0	0	4.06	0.59	3.37
Dihomo- γ -linoleni c acid	0	0	10.85	1.57	3.09
Arachidonic acid	0	0	10.27	1.49	0
Eicosatetraenoic acid	0	0	4.89	0.71	0
Eicosapentaenoic acid	0	0	2.68	0.39	0
Total amount of lipids	-	12.25	-	14.48	-

In this Example, gas chromatography analysis was made under the following conditions:

(Gas chromatography analysis condition)

Column: Supelco SP-2330, Fused Silica Capillary
5 Column, 30 m × 0.32mm ID, 0.2 µm;

Temperature: Inj: 240°C, Det: 250°C, Oven: 180°C for 3 min, 180°C → 220°C (2°C/min); and

Column flow rate: 30 cm/sec, Pressure: 200 kPa, Detector: FID.

10 Each peak in the chromatogram was determined by a retention time of methyl ester of normal fatty acids and GC-MASS (Hewlett Packard, HP-5973) analysis, and the proportions of the respective fatty acids were determined in accordance with a peak area. In Table 1, "Control" indicates a
15 control, "pSPB2368" indicates the pSPB2368-transformed tobacco, "pSPB1519" indicates the pSPB1519-transformed tobacco.

The results shown in Table 1 confirmed accumulation of dihomono-γ-linolenic acid in the tobacco that has incorporated
20 the pSPB1519 containing the filamentous fungus-derived genes (pSPB1519-transformed tobacco), but no accumulation of arachidonic acid. On the other hand, in the tobacco that has incorporated the pSPB2368 containing the *Marchantia*

polymorpha-derived enzyme genes (pSPB2368-transformed tobacco), accumulation of not only arachidonic acid but also eicosatetraenoic acid and eicosapentaenoic acid was confirmed. These results suggest that, in higher plants, the *Marchantia polymorpha*-derived enzymes are functionally superior to the filamentous fungus-derived enzymes in the ability to synthesize arachidonic acid and other polyunsaturated fatty acids using linoleic acid and α -linolenic acid as substrates.

Abbadi has reported that by introducing *Phaeodactylum tricornutum*-derived $\Delta 6$ desaturase and $\Delta 5$ desaturase, and a *Physcomitrella patens* chain elongase gene into tobacco and flax (*Linum usitatissimum*), 1.5% arachidonic acid was accumulated in a seed of tobacco, and 1.0% arachidonic acid was accumulated in a flax (Amine Abbadi et al. Plant Cell 16, 2734-2748, 2004).

In the present Example, by introducing *Marchantia polymorpha*-derived $\Delta 6$ desaturase, $\Delta 5$ desaturase, and chain elongase into tobacco, 10% or greater arachidonic acid was accumulated in a tobacco leaf. This result suggests that the pSPB2368-transformed tobacco in the present Example is capable of more efficiently synthesizing polyunsaturated fatty acids, as compared with the foregoing report.

Further, it has been reported that as a result of lipid modification of *Arabidopsis thaliana* using three types of genes: *Isochrysis galbana*-derived $\Delta 9$ chain elongase, *Englena gracilis*-derived $\Delta 8$ desaturase, and filamentous fungus-derived $\Delta 5$ desaturase, 6.6 mol% of arachidonic acid and 22.5 mol% of fatty acids having 20 or more carbon atoms with respect to the total lipids were contained in the leaf (Baoxiu Qi et al. Nature Biotechnology 22, 739-745, 2004). In this report, polyunsaturated fatty acids are synthesized through a modification pathway different from the pathway using the $\Delta 6$ desaturase, $\Delta 5$ desaturase, and chain elongase, and it was found that more polyunsaturated fatty acids could be accumulated when *Marchantia polymorpha*-derived enzymes were used, although a simple comparison cannot be made.

The pSPB2368-transformed tobacco having a 30% or greater modified fatty acid content with respect to the total lipids showed no morphological abnormalities. Further, since the pSPB2368-transformed tobacco has no problem in terms of fertility and bore a lot of seeds, it is believed that the ectopical increase of the polyunsaturated fatty acids has no significant effect on the growth and development of plants.

In the transgenic plants reported so far, up to about

20% of total lipids is polyunsaturated fatty acids having 20 or more carbon atoms. The value reduces to about 6% when only arachidonic acid is considered. However, as in the present Example, the use of *Marchantia polymorpha*-derived fatty acid synthetases makes it possible to go beyond this limitation and produce more polyunsaturated fatty acids in plants.

Specific embodiments or examples implemented in the best mode for carrying out the invention only show technical features of the present invention and are not intended to limit the scope of the invention. Variations can be effected within the spirit of the present invention and the scope of the following claims.

INDUSTRIAL APPLICABILITY

The present invention provides a $\Delta 5$ desaturase gene, a $\Delta 6$ desaturase gene, and a $\Delta 6$ chain elongase gene, which are obtained from a single species of *Marchantiales*. The three genes, when expressed together in a plant, function more desirably in the plant as compared with the case where genes obtained from organisms of different species are expressed. Further, since *Marchantiales* can be considered as a model plant of higher plants, the genes derived from *Marchantiales* can function more desirably in plants than genes derived from

non-plants.

Further, with a transformant according to the present invention, polyunsaturated fatty acids such as arachidonic acid or eicosapentaenoic acid (EPA) can be produced. More
5 advantageously, a transformant according to the present invention produces these fatty acids at low cost by an environmentally friendly process. The product arachidonic acid or EPA can be inexpensively marketed as a material with different purposes. When used as food, the transformant can
10 increase the value of the product with its high arachidonic acid or EPA content.

As described above, genes and proteins of the present invention are useful in producing arachidonic acid and EPA. Further, transformants that have incorporated genes of the
15 present invention are highly useful in the arachidonic acid or EPA production in pharmaceutical industry, food industry, and various other material industries. The usefulness of the transformant is particularly notable in agricultures when the transformant is a plant, because the transformation increases
20 arachidonic acid and EPA levels in plants.
